Project Originator: **Zébulon Goriely**  
Supervisor: **Prof. Paula Buttery and Dr. Andrew Caines**

## Original Aims of the Project

Language has evolved and therefore probably gave an evolutionary advantage to the individuals that exhibited it. According to Cangelosi and Parisi (1998), it is difficult to investigate the evolutionary origin of language and the selective pressures that may have originated language due to the limited evidence available. They propose using computer simulations of evolutionary scenarios to investigate this. In the paper referenced, they describe a simulated toy world where agents controlled by neural networks interact with an environment of mushrooms that are edible and poisonous. Exploring this simulation is the basis of my project.

## Work Completed

I implemented the mushroom-world simulation and explored three populations of feed-forward neural networks; one without language, one with an externally imposed language and one with an evolved language. To simulate evolution, I implemented a genetic algorithm to allow the fittest members of each generation to reproduce. The state of the simulation was saved at each generation in order to plot the fitness of the three populations, plot the quality of the language produced and investigate behavioural tests. To conclude the project, I compared these findings with Cangelosi and Parisi (1998).

# Chapter 1

## Introduction

*Introduction here, start again as if abstract does not exist. Include your contributions in bullet point format. End with paragraph describing structure of the rest of the paper*

### 1.1 Motivations

*High level, still cite, why does this interest us from a scientific perspective. What could we learn.*

- Want to investigate evolutionary origin of language
- Difficult to investigate due to limited evidence, so computer simulations could be good
- Investigation of cultural vs sexual mechanisms
- Artificial life
- Main question - how can language evolve when it has a purely informative function and so advantageous to receiver but not to the producer?
- Reference Clark (1993) for what an efficient language is

### 1.2 Prior Work

*State what similar work has been done before and since what i'm trying to replicate. Also a continuation of the motivation. Why does this paper in particular interest you. Focus more on their prior work. Talk about work that has continued.*

- Symbol grounding
- Language games
- Mushroom world

## 1.3 Project Overview

# Chapter 2

## Preparation

*This chapter covers the background to my project in Sections 2.1 to 2.3, then evaluates the requirements for the project in Section 2.4. I discuss the starting point of my project in Section 2.5 and the software engineering techniques used in Section 2.6.*

### 2.1 Mushroom World

To explore how the introduction of language may affect a population’s fitness, we need a simulated environment in which to test these changes. This “mushroom world” was described by Cangelosi and Parisi (1998), inspired by the use of signals to communicate information about food location and quality present in many species.

The organisms will live in an environment populated by two different types of mushroom; edible and poisonous. The organisms will reproduce based on their ability to eat edible mushrooms and avoid the poisonous ones. They will need to learn to categorise the two mushrooms and respond accordingly by moving towards and eating the edible mushrooms and moving away from the poisonous mushrooms.

To ensure this categorisation isn’t trivial for the organisms, the mushrooms will have different properties. Edible mushrooms will resemble each other but won’t be identical and likewise for poisonous mushrooms.

Each organism will live in an environment of  $20 \times 20$  cells containing 20 randomly distributed mushrooms; 10 of which are poisonous and 10 of which are edible. They will be able to explore this world in 15 epochs of 50 simulation cycles each; in each new epoch the world is ‘reset’, the position of the entity reset in a new environment with 20 new randomly distributed mushrooms. An example of this world can be seen in Figure 2.1.

These constants are fairly arbitrarily chosen by Cangelosi and in later sections I will explore the effects of changing them, but for now I can intuitively explain some of these choices. The 15 epochs are used to average out the randomly generated positions of mushrooms so that it is really the behaviour of the organism that is being tested, not the random choice of environment. The 50 simulation cycles along with the specific dimensions

Figure 2.1: An organism (▲) in the simulation environment with edible (E) and poisonous (P) mushrooms.

of the environment ensures that the organism will likely be able to reach at least one edible mushroom but will unlikely be able to eat all edible mushrooms in time. This encourages productive strategies to search for edible mushrooms within the limited time available. Intuitively, this reflects the limited time that living organisms have to search for food in their lifetimes. A full list of constants can be seen in Table 2.1.

## 2.2 Entities

In the simulation, organisms are represented by *entities*. Entities can *perceive* their surroundings and *act* accordingly.

The perception is composed of three senses; the entity can sense the *direction* of the nearest mushroom (a sort of ‘smelling’ sense), can see the *properties* of mushrooms it is adjacent to (a ‘visual’ sense) and can receive *signals* from other entities (a ‘auditory’ sense). The adjacency restriction to the visual sense means that entities without any other signals must approach mushrooms in order to be able to categorise them.

The action is composed of two responses; the *movement* of the entity and the *signal* it produces. The movement is restricted to four options; moving one cell forwards, turning 90° left, turning 90° right and doing nothing. Instead of incorporating some ‘eat’ action, a mushroom will be considered eaten when the entity moves into the cell that the mushroom occupies. The signal is used to communicate information to other entities when we explore

adding language to the simulation.

The simulation should also incorporate evolution; some process by which the fittest entities of a species reproduce to pass on their behaviour to a new generation, with some degree of mutation. This will allow a population's average fitness to improve over many generations. From this abstract description of entities, I can consider how this system may be designed.

### 2.2.1 Feed-Forward Neural Networks

Inspired by the biological neural networks that constitute animal brains, *artificial neural networks* are an appropriate choice for modelling the behaviour of these entities. Neural networks are composed of nodes (artificial neurons) which loosely model the neurons in a biological brain. Each node processes a signal by computing a non-linear function of the sum of the inputs. By organising these nodes into layers, signals can travel through from the input layer to the output layer. This is a *feed-forward* neural network as there are no loops present to allow a signal to traverse a layer multiple times. A *fully-connected* neural network feeds the output of every node in a layer into the input of every node in the next layer.

Each node computes an input using a *propagation function* as a weighted sum of the outputs of predecessor nodes, incorporating a *bias* added to the result of the propagation. An *activation function* can then be applied to produce the output of the node. As Cangelosi does not describe which activation function was used in his paper, I will explore the use of three common functions:

- Identity:  $f(x) = x$
- Sigmoid:  $f(x) = \frac{1}{1+e^{-x}}$
- ReLU<sup>1</sup>:  $f(x) = \begin{cases} 0 & \text{for } x \leq 0 \\ x & \text{for } x > 0 \end{cases}$

The entities can be represented by a fully-connected feed-forward neural network. The *perception* of the entity acts as the input of the neural network with the output treated as the *action* chosen by the entity. To increase the computational abilities of the entity, I also include a layer of hidden nodes to allow for more complex decision making (INCLUDE REASON WHY HERE). This structure can be seen in Figure 2.2. By altering the weights and biases used by the network, the entity will respond differently to the perceptual inputs, producing different behaviours.

### 2.2.2 Alternative Structures

- talk about linear regression

---

<sup>1</sup>ReLU stands for Rectified Linear Unit

Figure 2.2: Structure of a fully-connected ANN to control entity behaviour

- talk about svms
- talk about more complex neural networks

### 2.2.3 Genetic Algorithm

Similarly to how an artificial neural network is a natural implementation for simulating the behaviour of an entity, the *genetic algorithm* is a natural implementation for simulating the population dynamics of a population of such entities. Just as artificial neural networks are inspired by animal brains, the genetic algorithm is inspired by the process of natural selection which is the very process that we want to simulate.

Generally, a genetic algorithm takes a *population* of candidate solutions to an optimisation problem and evolves the population towards a better solution. Each candidate has a set of properties, a *genetic representation* which can be mutated and altered. The evolution starts from a population of randomly generated individuals and proceeds iteratively. For each *generation*, the *fitness* of each individual is calculated. The more fit individuals are selected and their genomes modified to form a new generation, used in the next iteration.

This maps neatly to our problem. The *population* used by the algorithm is simply a group of entities. The *genetic representation* of the entities is the set of weights and biases used by each neural network. The *fitness* score,  $F$  will be calculated according to the number of edible and poisonous mushrooms eaten by the entity during the simulation,  $E$  and  $P$  respectively:

$$F = 10E - 11P$$

This rewards entities that eat edible mushrooms and punishes those that eat poisonous mushrooms. The difference in weight between these two scores gives a greater reward to the entities that eat more edible mushrooms than poisonous mushrooms as it punishes the greedy strategy of simply eating as many mushrooms as possible.

Finally, the reproduction occurs by selecting a percentage of the population with the highest fitness score and producing a small set of offspring for each of these individuals by randomly altering a percentage of the weights and biases in the neural network. In Cangelosi and Parisi (1998), the top 20% of entities are selected from a population of 100. Each of these entities produces five entities by randomly mutating 10% of their weights and biases, producing a new generation of 100 entities. These introduce two new constants, as described in Table 2.1.

### 2.2.4 Population types

To carry out the investigation of whether introducing language to a population increases its fitness, I will implement three different populations in the simulation. As described by Cangelosi and Parisi (1998), these three populations differ in how the communication signals are used in the simulation environment. The three population types are:

- No Language
- External Language
- Evolved Language

The population with no language acts as a baseline. The audio input to the neural network controlling the entity is set to a constant and the audio output is ignored. These entities cannot perceive the properties of the mushrooms unless they are adjacent; unlike the other populations they are not assisted by some linguistic signal.

The population with an externally provided language is slightly different. Here, I imagine that at the closest mushroom to the entity, another entity is present and can see the properties of the mushroom, generating an appropriate audio signal for the primary entity. The language is “externally provided” because I will enforce that one signal is used for edible mushrooms and another is used for poisonous mushrooms without actually involving another entity in the simulation.

The population with an evolved language is similar to the External Language population, but I will not enforce the use of particular signals. Instead, I will allow the population to derive its own signals. This will be done by pairing the primary entity with another randomly chosen entity at each simulation cycle. This second entity will be given same inputs as the primary entity as well as the properties of the closest mushroom, no matter the distance. This entity labels the mushroom for the primary entity. The audio output of this second entity will be used as the audio input to the primary entity; simulating a one-word utterance.

The differences between these populations can be seen in Figure 2.3.

Figure 2.3: Differences in simulation structure for the three population types

Constant	Description	Default Value
dim_x	The width of the simulation environment	20
dim_y	The height of the simulation environment	20
num_mushroom	The number of mushrooms placed in the environment	20
num_epochs	Number of epochs for each simulation	15
num_cycles	Number of simulation cycles per epoch	50
num_entities	Number of organisms in a population	100
num_generations	Number of times a population will reproduce	1000
mutate_percentage	The percentage of weights to mutate in reproduction	10
percentage_keep	The percentage of organisms chosen to reproduce	20

Table 2.1: A description of the constants and default values used for the simulation.

## 2.3 Simulation Analysis

### 2.3.1 Generational Fitness

As discussed in section 2.2.3, the fitness score for each entity describes its success in distinguishing between edible and poisonous mushrooms and correctly eating the former and avoiding the later. Cangelosi and Parisi (1998) plot the average fitness across 1000 generations to compare the three population types discussed in section 2.2.4. This will be the primary way that I compare different runs of the simulation.

### 2.3.2 Efficiency of Language

Cangelosi and Parisi (1998) were also interested in the *efficiency* of the language produced by these organisms. They gave three requirements for a population having an efficient language:

1. Functionally distinct categories (e.g. mushroom type) are labelled with distinct signals
2. A single signal tends to be used to label all instances within a category
3. All the individuals in the population tend to use the same signal to label the same category

These requirements were based on principles that Clark (1995) argues govern a child's acquisition of a lexicon. To investigate the language produced by different populations, Cangelosi used a "naming task". In this controlled experiment, each entity in a population is exposed to the entire set of mushrooms (10 edible and 10 poisonous) in four locations (forward, left, backwards and right). This produces 80 signals per entity. The frequency distribution for the signals produced for edible and poisonous mushrooms by all entities can be plotted and this will be the second way I analyse the simulations.

Cangelosi and Parisi (1998) also described the calculation of a "Quality Index" (QI) to describe the efficiency of a language. The QI is calculated as follows:

$$d_{\text{poisonous}} = \sum_{i=1}^8 |x_i - x_e|$$

$$d_{\text{edible}} = \sum_{i=1}^8 |y_i - y_e|$$

$$\text{QI} = \sum_{i=1}^8 |x_i - y_i| - k \times \min(d_{\text{poisonous}}, d_{\text{edible}})$$

$x_i$  and  $y_i$  are the frequencies of signals used for poisonous and edible mushrooms respectively, as calculated from the "naming task" and  $x_e$  and  $y_e$  are the expected percentages in the case of a flat distribution.  $k$  is a constant to weight the effect of the internal dispersion values  $d_{\text{poisonous}}$  and  $d_{\text{edible}}$  and is typically 1.

These dispersion values measure the variance of the distribution of signals used for the same category (edible or poisonous). This captures the use of synonyms, as these values are highest when only one signal is used for the category.

The first part of the QI equation captures the principle of contrast (use of one word for each class of mushrooms) as it is highest when different signals are used for each category. By adding(?) this to the smaller of the two dispersion values, we get a score that captures the idea of an 'efficient' language.

This will be the third way that I analyse the simulations; in particular I will examine the correlation between language efficiency and population fitness. In particular, it will be interesting to see if a correlation exists in the No Language population, despite not using any form of communication, as this would imply the parallel development of cognitive ability with linguistic ability.

LOOK INTO THIS EQUATION - A PLUS MAKES A LOT MORE SENSE

## 2.4 Requirements Analysis

My project involves reimplementing the simulation described in sections 2.1 - 2.2 and analysing this simulation in regards to the three metrics described in section 2.3. The requirements for this project can then be divided into two sections; implementing the simulation and constructing the means of analysis my implementation against the findings in Cangelosi and Parisi (1998).

### Implementing the Simulation

1. Have a simulation environment with a world grid populated by poisonous and edible mushrooms. The simulation loop should be divided into regular ‘epochs’.
2. Have entities capable of navigating the environment, taking actions in each simulation cycle controlled by feedforward neural networks; with the structure described in section 2.2.1.
3. Have a genetic algorithm that runs after all agents complete the simulation, as described in section 2.2.3.
4. Have three populations, one without language, one with an externally imposed language and one with an evolved language involving speaker-listening pairs, as described in section 2.2.4.

### Analysis of the Simulation

1. Have plots of the average fitness over the number of generations to compare between the three populations.
2. Have behavioural tests to investigate the behaviour of random individual organisms at specific generations.
3. Have plots the frequency distribution of the different signals produced by the individuals with the evolved language using a ‘naming task’.
4. Calculate the Quality Index (QI) of the language produced by the population without language and the population with an evolved language to investigate the genetic advantage of producing productive signals.

5. Investigate the correlation between QI of the language and the fitness of the species to determine if change in the language or in the categorisation skill of the entities affects the linguistic ability.

## 2.5 Starting Point

The implementation of the project is based on Cangelosi and Parisi (1998) which I familiarised myself with before beginning the project and in the early preparatory phases.

This project builds on concepts of simulations; I had a small amount of experience in programming simulations from an A-Level project in 2016. Before the project, I also read *Simulating the Evolution of Language* (?) to give me an overview of the techniques used in this field.

This project builds on some of the content covered in the Artificial Intelligence course and the Formal Models of Language course from Part 1b. In particular, I had no experience with neural networks before beginning this project and all the code for the project was written from scratch and within the dates of the project.

## 2.6 Software Engineering

### 2.6.1 Languages and Libraries

I chose Python for my project due to the ease of programming, my experience with it and the availability of good libraries for numerical analysis and plotting. To avoid code duplication, I made use of a few libraries:

1. To perform some scientific computing, I used SciPy<sup>2</sup>.
2. For the plotting of the analysis of the simulation, I used Matplotlib<sup>3</sup>.
3. For producing unit tests, I used pytest<sup>4</sup>.

### 2.6.2 Project Management

During implementation, I followed an agile development process. An initial project plan was formulated at the beginning of the project with a list of tasks to complete. These tasks were compiled into a Kanban board, with sections for Todo, In Progress, Testing/Documenting and Completed. My project plan divided the timeline of my project into a series of 2-3 week sprints, each with associated deadlines and milestones. At the

---

<sup>2</sup><https://www.scipy.org/>

<sup>3</sup><https://matplotlib.org/>

<sup>4</sup><https://docs.pytest.org/>

beginning of each sprint I selected the tasks to complete in order to meet these deadlines and successfully pass each milestone, often completing additional tasks when work was completed early.

This agile process allowed me to ensure I was on track with my project. In fact, the success criteria proposed at the start of the project was met very early on in the timeline, allowing me to focus on refining the project and work on my extensions.

### 2.6.3 Version Control

For version control, I used Git to track change with a remote repository on GitHub<sup>5</sup>. This served as a backup, allowed me to revert to previous iterations of my code and allowed me to work on multiple computers. In particular, it allowed me to deploy my project to the University's High Performance Computing service for running the simulations, as discussed below. In addition, I also performed hardware backup to a hard drive twice a week.

### 2.6.4 Development tools

I made use of a number of tools to streamline my development process:

1. I used Travis<sup>6</sup> for continuous integration. With each commit, a script would automatically run all my unit tests and check my code for correct formatting.
2. I used pylint<sup>7</sup> to lint my code. This allowed me to ensure my code was readable and that I was complying with Google's python style guide<sup>8</sup>.
3. I used yapf<sup>9</sup> to format my code consistently. I implemented a git hook to automatically format my code with each commit; the formatting was further checked by my Travis script.

### 2.6.5 Development environment

I used Visual Studio Code<sup>10</sup> as a development environment, due to the friendly interface and useful set of plugins that integrated nicely with git, pylint and pytest.

To run my simulations, I used the University's High Performance Computing service. I created a set of Slurm scripts with a bash script that would allow me to schedule 30 simulations to run at once and independently. The results of these simulations were saved to files that I could copy to my local filesystem over SSH.

### **2.6.6 Code License**

My source code is publicly available on GitHub with a README to explain how to use it. The project is licensed under the MIT license, for free modification and reuse while limiting my liability. It also preserves the copyright notice.

## **2.7 Summary**

# Chapter 3

## Implementation

*Start with UML, high level overview*

*Talk about problems with trying to replicate, not knowing what you set.*

# Chapter 4

## Evaluation

*Show graphs, run by run etc.*

*Variance is interesting to discuss*

*Could also be interesting to query what happens in an elbow in the graph - visual and a bit subjective. Three categories - those that don't take off, those that suddenly take off and those that gradually take off.*

*Variance in each run, consequences of initialisation/activation, bigger questions about how reliable neural networks are, whether they're a good model for language evolution.*

## Chapter 5

## Conclusion

# Bibliography

**Director of Studies:** Prof. Alastair Beresford

**Project Overseers:** Prof. Pietro Lio & Dr. Robert Mullins

### Introduction

Language has evolved and therefore probably gave an evolutionary advantage to the individuals that exhibited it. As Angelo Cangelosi and Domenico Parisi described in a 1998 paper<sup>1</sup>, it is difficult to investigate the evolutionary origin of language and the selective pressures that may have originated language due to the limited evidence available. They propose using computer simulations of evolutionary scenarios to investigate this. In the paper referenced, they describe a simulated toy world where agents controlled by neural-networks interact with an environment of mushrooms that are edible and poisonous. This simulation and the ideas explored in the paper will be the basis for my project.

In the paper, Cangelosi and Parisi use small feed-forward neural networks to control the behaviour of each agent. The weights are initially random; a genetic algorithm is used

---

<sup>1</sup><https://doi.org/10.1080/095400998116512>

to improve the fitness of the species over many generations. The agents are also given linguistic abilities; input and output nodes of the neural networks produce signals that allow for communication.

By creating three different populations (one without language, one with an externally imposed language and one with an evolved language) we can investigate the evolutionary advantage of language. Furthermore, it allows us to investigate a key question posed in the paper: *“Since language requires the parallel evolution of linguistic production and linguistic comprehension, how can language evolve when it has a purely informative function and therefore it is advantageous to the receiver but not the producer?”*

For this project, I will re-implement the simulation described. I will then create analysis tools to investigate the findings of the paper to see if I observe the same results.

## Starting Point

I have a small amount of experience in programming simulations; for my A-Level project in 2016, I created a simulation of virus propagation between mosquito and human agents in the Unity game engine.

I do not have any experience programming neural networks, however, I am confident that I understand the backpropagation algorithm and basic neural network structure through the Artificial Intelligence course I took last year. In the papers I plan to reference, Cangelosi very clearly describes the structure of the neural networks he uses and I am confident that I will be able to follow his work.

Over the summer I read a book titled *Simulating the Evolution of Language* which gave me an overview of the techniques used in this field. Alongside the *Formal Models of Language* course that I took last year, I now have a sufficient base of understanding to begin this project.

## Work to be Done

The work for this project can be roughly divided into two stages; implementing the simulation and constructing the means of evaluating my implementation against the findings in the original paper. I will also regularly be creating tests to evaluate my simulation.

### Implementing the Simulation

1. Set up the simulation environment by creating the world grid and implementing the properties of poisonous and edible mushrooms. Create the simulation loop divided into regular ‘epochs’.
2. Create the agents for the simulation, giving them position and energy properties.

3. Implement feedforward neural networks to control the behaviour of the agents; input units to identify the location of the nearest mushroom, visual perception units to observe mushroom properties (only when close enough) and signal perception units for when language is implemented. The output units control the movement of the agent and production of signals. There will also be hidden units.
4. Implement the genetic algorithm that runs after all agents complete the simulation. The fittest agents are determined by the energy level (based on eating edible mushrooms and avoiding poisonous mushrooms). The fittest agents are then chosen for asexual reproduction, producing offspring that have genetic mutations in the form selecting a percentage of the weights to change by a random amount.
5. Create two different populations, one without language (where the signal perception units are always set to the same, constant value) and one with an externally imposed language (where the signal perception units are set to one of two signals depending on the type of the nearest mushroom).
6. Create a third population with an evolved language. Instead of externally imposed signals, in each simulation cycle one of the other agents is randomly selected as the ‘speaker’ and its output is connected to the input signal perception units of the ‘listener’.

## Analysis

1. Plot the average fitness over the number of generations to compare between the three populations.
2. Produce some behavioural tests to investigate the behaviour of random individual organisms at specific generations.
3. Plot the frequency distribution of the different signals produced by the individuals with the evolved language using a ‘naming task’.
4. Calculate the Quality Index (QI) of the language produced by the population without language and the population with an evolved language to investigate the genetic advantage of producing productive signals. The QI evaluates the efficiency of a language based off of three criteria; (1) functionally distinct categories are labeled with distinct signals, (2) a single signal tends to be used to label all the instances within a category and (3) all the individuals in the population tend to use the same signal to label the same category.
5. Investigate the correlation between QI of the language and the fitness of the species to determine if change in the language or in the categorisation skill of the agents affects the other ability.

## Testing

To evaluate my project and ensure that my simulation implementation is functional, I will create an ensemble of unit tests for each of the tasks above. These will be created in parallel as I develop each part of the implementation. For the simulation, this will involve small examples or scenarios to show that each part of the simulation is fully functional.

## Success Criterion

The project will be deemed a success if I can implement the simulation as described in the tasks above (evaluated by my unit tests) and if I can implement the analysis tools to compare the findings of my implementation to the findings of the original paper.

## Timetable and Milestones

I've broken down this timetable into two and three week intervals. At the end of December, I will be writing my Progress Report and simultaneously making adjustments to the timetable as needed.

### 25<sup>th</sup> October – 10<sup>th</sup> November

*Middle of Michaelmas Term. Includes first deadline for NLP coursework.*

**Task:** Create a high-level design of the system. Set up the project files with a version-control system. Experiment with creating small simulations in python and do suitable research into Neural Network libraries.

**Milestones:** Have a git repository with project files. Have a design plan with specific details of the simulation confirmed.

### 11<sup>th</sup> November – 24<sup>th</sup> November

*Middle of Michaelmas Term.*

**Task:** Complete implementation tasks 1 and 2 as described above. Experiment with adding Neural Networks to control the behaviour of the agents.

**Milestones:** Have a working simulation environment with poisonous and edible mushrooms. Have agents with positions and energy values but no functional neural networks yet.

## 25<sup>th</sup> November – 8<sup>th</sup> December

*End of Michaelmas Term. Includes second and third deadline for NLP coursework.*

**Task:** Complete implementation tasks (3). Start working on implementation task (4).

**Milestones:** Have the agents successfully controlled by neural networks. Be able to run an entire lifespan of one agent within the simulated world.

## 9<sup>th</sup> December – 22<sup>nd</sup> December

*Christmas holiday. Will likely be in Cambridge to help with Queens' interviews.*

**Task:** Complete implementation tasks (4), (5) and (6). Also aim to complete analysis tasks (1) and (3).

**Milestones:** Have a fully functional simulation that allows for running a thousand generations of a population of agents. Have three different populations to compare; one without language, one with an externally imposed language and one with an evolved language. Have a tool to graph the average fitness of each population over the number of generations and another tool to view the probability distribution of the signals chosen for the evolved language over the number of generations.

## 23<sup>rd</sup> December – 12<sup>th</sup> January

*Christmas holiday. Will take a break to revise Michaelmas courses and to spend time with family.*

**Task:** Complete analysis task (2). Write the Preparation chapter of the Dissertation. Review the timetable for the remainder of the project and adjust in light of experience so far. If ahead of schedule, plan time for extensions. Start to plan tests cases.

**Milestones:** An outline of the dissertation document with a completed Preparation section.

## 13<sup>th</sup> January – 2<sup>nd</sup> February

*Start of Lent term. Will have regular labs for Mobile Robot Systems.*

**Progress Report Deadline:** 31<sup>st</sup> January

**Task:** Write the Progress Report. Start to fill out the Implementation chapter of the Dissertation. Complete analysis tasks (4) and (5).

**Milestones:** Progress report submitted and entire project reviewed both personally and with overseers. Have tools to plot the Quality Index of the evolved language against the fitness of the population. At this point, all the tasks in the **Work to Do** section will have been completed, satisfying the **Success Criteria**.

### 3<sup>rd</sup> February – 23<sup>rd</sup> February

*Middle of Lent term. Both deadlines for the Mobile Robot Systems assignments.*

**Task:** Begin analysis of the simulation. Begin to work on extensions to the project, keeping in mind time needed to write the Dissertation.

**Milestones:** Have the start of a test suite with a series of diagrams to use to evaluate my implementation.

### 24<sup>th</sup> February – 15<sup>th</sup> March

*End of Lent term. Deadline for the Mobile Robot Systems mini-project report.*

**Task:** Complete testing. Evaluate the outcomes of the tests against the findings in the original paper. At this point, the second half of the **Success Criteria** will have been achieved. If needed, revise the implementation to be clean, documented and concise. Work on other extensions.

**Milestones:** Examples and test cases run with results collected. Code should perform a variety of interesting tasks and should be in a state that in the worst case it would satisfy the examiners with at most cosmetic adjustment

### 16<sup>th</sup> March – 5<sup>th</sup> April

*Start of Easter holiday. Might stay in Cambridge for part of it to work. Will balance revision and work on the project.*

**Task:** Complete work on any extensions. Draft the Evaluations and Conclusions chapters of the Dissertation.

**Milestones:** Extensions almost complete. Skeleton of entire Dissertation in place.

### 6<sup>th</sup> April – 19<sup>th</sup> April

*End of Easter holiday. Might get back to Cambridge early to work. Will balance revision and work on the project.*

**Task:** Complete the Implementation and Introduction chapters of the Dissertation. Send the full draft to Director of Studies and Supervisors by 21st of April.

**Milestones:** Dissertation essentially complete, with large sections of it proof-read by Supervisors and possibly friends and/or Director of Studies.

### 20<sup>th</sup> April – 8<sup>th</sup> May

*Start of Easter Term. Will be balancing revision, lectures and final work on the project.*

**Final Deadline:** 8<sup>th</sup> May

**Task:** Finish Dissertation, preparing diagrams for insertion. Review the whole project, checking the Dissertation and spending the final few days on whatever is in greatest need of attention. Aim to submit the dissertation at least a week before the deadline.

**Milestone:** Submission of Dissertation

## Possible Extensions

### Graphic Visualisation

As a side extension, I could implement a visual interface to watch the life of one agent within the simulation. This would involve rendering a simple 2D world with textures for the agents and mushrooms. This could be expanded further by adding a User Interface for setting up the simulation and having windows showing the progress as it occurs live.

### Symbolic Theft vs. Sensorimotor Toil

In a 2000 paper<sup>2</sup>, Cangelosi and Harnad use a similar same toy world of mushrooms and foragers to place two ways of acquiring categories in direct competition with each other. They compare “sensorimotor toil” (where categories are acquired through real-time, feedback-correct, trial and error experience) to “symbolic theft” (where new categories are acquired by hearsay from boolean combinations of symbols *describing* them). They find that the origins of natural language could be explained by the apparent infinitely superiority of a hybrid symbolic/sensorimotor combination compared to purely sensorimotor precursors.

As an extension, I could expand my simulation to investigate the findings of this paper. This involves implementing a more complicated neural network, adding supervised learning through back-propagation, implementing more sophisticated mushroom features and expanding the simulation to host multiple populations at once.

### Investigating the Evolution of Syntax

In a 1999 paper<sup>3</sup>, Cangelosi expands the toy mushroom world simulation further to investigate how languages that use combinations of words (such as the “verb-object” rule) can emerge by auto-organisation and cultural transmission. Mushrooms are either edible or poisonous but also have one of three colours - the edible mushrooms of a particular colour correspond to a particular action in response.

<sup>3</sup>[https://link.springer.com/chapter/10.1007/3-540-48304-7\\_86](https://link.springer.com/chapter/10.1007/3-540-48304-7_86)

In this extended simulation, after the first 300 generations parents and children co-exist within the simulated world. Parents teach the evolved language to their children. Children undergo a Listening Task (where parents describe the closest mushroom) and a Naming Task (where the mushroom name is used for supervised learning through backpropagation).

This is a substantial increase in complexity but allows would allow me to investigate the evolution of a more complex language.

## Resources Declaration

For this project, I plan to use my computer, (2.8 GHz CPU, 16 GB RAM, 750GB Flash Storage, macOS Mojave). The code will be regularly pushed to a GitHub repository to be able to recover from failure or loss on my local machine. I will also create weekly backups on an external hard-drive to provide another source of recovery. Should my machine fail, I will be able to continue working on an MCS machine. I accept full responsibility for this machine and I have made contingency plans to protect myself against hardware and/or software failure.

I will also need to use the high powered computer when running large simulations to save processing time.
